#### Question 1

### 15 points

A problem with the Newton-Raphson algorithm is that it needs the derivative f'. If the derivative is hard to compute or does not exist, then we can use the *secant method*, which only requires that the function f is continuous.

Like the Newton-Raphson method, the **secant method** is based on a linear approximation to the function f. Suppose that f has a root at a. For this method we assume that we have two current guesses,  $x_0$  and  $x_1$ , for the value of a. We will think of  $x_0$  as an older guess and we want to replace the pair  $x_0$ ,  $x_1$  by the pair  $x_1$ ,  $x_2$ , where  $x_2$  is a new guess.

To find a good new guess x2 we first draw the straight line from  $(x_0, f(x_0))$  to  $(x_1, f(x_1))$ , which is called a secant of the curve y = f(x). Like the tangent, the secant is a linear approximation of the behavior of y = f(x), in the region of the points  $x_0$  and  $x_1$ . As the new guess we will use the x-coordinate  $x_2$  of the point at which the secant crosses the x-axis.

The general form of the recurrence equation for the secant method is:

$$x_{i+1} = x_i - f(x_i) \frac{x_i - x_{i-1}}{f(x_i) - f(x_{i-1})}$$

Notice that we no longer need to know f' but in return we have to provide two initial points,  $x_0$  and  $x_1$ .

Write a function that implements the secant algorithm. Validate your program by finding the root of the function  $f(x) = \cos(x) - x$ . Compare its performance with the Newton-Raphson method – which is faster, and by how much? For this example  $f'(x) = -\sin(x) - 1$ .

```
### Newton-Raphson Method
# Arguments
# - Initial guess
# - The function of which to find the root
# - The derivative of the function
```

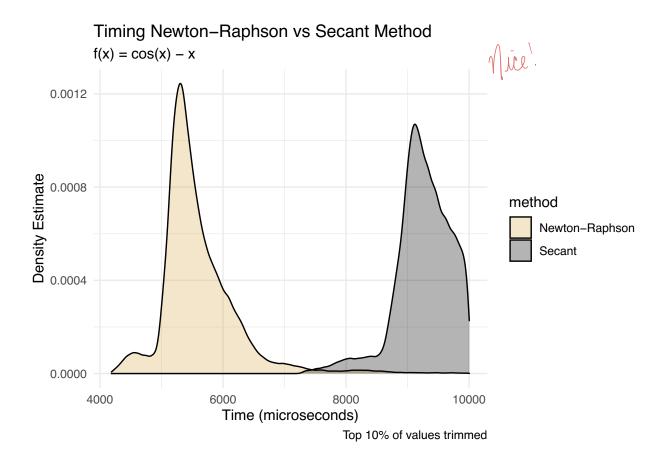

```
add a condition
             newton_raphson <- function(x, f, f_prime) {</pre>
to make sure the
             \rightarrow while (abs(f(x)) > 1e-8)
number of is within
               {
                                    make tolerance an input
  terational
                  # Update x by linear approximation
   MAX-ITER
                  x \leftarrow (x - (f(x) / f_prime(x)))
                return(x)
              ### Secant Method
              # Arguments
              # - First guess
              # - Second quess
              # - The function of which to find the root
              secant_method <- function(x0, x1, f) {</pre>
                while (abs(f(x1)) > 1e-8)
                  # Calculate slope between the points
                  m \leftarrow (f(x0) - f(x1)) / (x0-x1)
                  # Set x1 to x0
                  x0 <- x1
                  # Solve for new x1 with linear approximation
                  x1 \leftarrow (x1 - (f(x1) / m))
                }
                return(x1)
              }
              # Compare the Newton-Raphson method to the Secant method.
              # Both give the same solution and agree with the built-in
              # uniroot() function
              newton_raphson(1, function(x) cos(x) - x, function(x) - sin(x) - 1)
              ## [1] 0.7390851 \( \square$
              secant_method(1, 2, function(x) cos(x) - x)
              ## [1] 0.7390851 V
              uniroot(function(x) cos(x) - x, interval=c(-50,50), tol = 1e-8)$root
              ## [1] 0.7390851 V
              # Time the two functions for 1e5 iterations each
              timing <- microbenchmark(</pre>
                newton_raphson(1, function(x) cos(x) - x, function(x) - sin(x) - 1),
                secant_method(1, 2, function(x) cos(x) - x),
                times=1e5
              )
              timing
              ## Unit: microseconds
              ##
                                                                                           expr
              ## newton_raphson(1, function(x) cos(x) - x, function(x) -sin(x) -
                                                                                            1) 4.186
```

```
## secant_method(1, 2, function(x) cos(x) - x) 7.266
## lq mean median uq max neval
## 5.250 5.91221 5.465 5.853 2884.685 1e+05
## 9.076 10.11932 9.395 9.858 12344.298 1e+05
```

We see that the Newton-Raphson method is faster on average, with a median time of 5.5 microseconds compared to 9.3 microseconds for the Secant method.

The plots below show the distribution of times.

```
# Put the timing data into a data frame
df <- tibble(time = timing$time, method = timing$expr)</pre>
# Rename to nicer names for plotting
df$method <- recode(</pre>
       df$method,
       `newton_raphson(1, function(x) cos(x) - x, function(x) -sin(x) - 1)` = "Newton-Raphson",
       `secant method(1, 2, function(x) cos(x) - x)` = "Secant"
# Plot the data using a KDE plot

# Question 2

# 20 points

The game of craps is played as follows (this is simplified). First, you roll two six-sided dice; let x be the sum of the dice on the first roll. If x = 7 or 11 you win, otherwise you keep rolling until either you get x again, in which case you also win, or until you get a 7 or 11, in which case you lose.

Write a program to simulate a game of craps. You can use the following snippet of code to simulate the roll of two (fair) dice:

```
# Returns the roll of two dice rolls
# and prints the value of the roll
roll <- function(){
  roll <- sum(ceiling(6*runif(2)))
  print(paste("You rolled ", roll))
  return(roll)
}</pre>
```

1. The instructor should be able to easily import and run your program (function), and obtain output that clearly shows how the game progressed. Set the RNG seed with set.seed(100) and show the output of three games. (lucky 13 points)

```
return(1)
               }
               else{
                 while(TRUE){
                   x <- roll()
                   if(x==first_roll){
                     print("YOU WIN!")
                     return(1)
                   else if (x \%in\% c(7,11)){
                     print("YOU LOSE!")
                     return(0)
                   }
                 }
              }
             }
             # Creates a silent version of craps() using purrr:quietly()
             # The output is stored in $result
             quiet_craps <- quietly(craps)</pre>
             # Test on three games
             set.seed(100)
             for (i in 1:3){
use replicate ()
               print(paste("Game ", i))
               craps()
               }
             ## [1] "Game 1"
             ## [1] "You rolled
             ## [1] "You rolled 5"
             ## [1] "You rolled
                                 10"
             ## [1] "You rolled 5"
             ## [1] "You rolled
             ## [1] "You rolled
             ## [1] "You rolled 9"
             ## [1] "You rolled 5"
             ## [1] "You rolled 11"
             ## [1] "YOU LOSE!"
             ## [1] "Game 2"
             ## [1] "You rolled 6"
             ## [1] "You rolled
             ## [1] "You rolled 9"
             ## [1] "You rolled
                                 ,11"
             ## [1] "YOU LOSE!" 🗸
             ## [1] "Game 3"
             ## [1] "You rolled 6"
             ## [1] "You rolled
```

wuld also

## [1] "YOU LOSE!" 🗸

2) wat! +7/1

1. Find a seed that will win ten straight games. Consider adding an argument to your function that disables output. Show the output of the ten games. (7 points)

```
seed <- 0
while(TRUE){
    set.seed(seed)
    results <- map_dbl(1:10, ~quiet_craps()$result) # Simulate 10 games
    if (sum(results) == 10) {
        print(seed)
        break
    }
    else{
        seed <- seed + 1
    }
}</pre>
```

## [1] 880

We see that the seed 880 will produce 10 wins in a row.

```
# Verify that the seed produces 10 wins in a row
set.seed(880)
map_dbl(1:10, ~craps())
```

```

### Question 3

### 5 points

This code makes a list of all functions in the base package:

```
objs <- mget(ls("package:base"), inherits = TRUE)
funs <- Filter(is.function, objs)</pre>
```

Using this list, write code to answer these questions.

- 1. Which function has the most arguments? (3 points)
- 2. How many functions have no arguments? (2 points)

Hint: find a function that returns the arguments for a given function.

```
# A function that takes a function and returns the number of arguments
num_args <- function(f){</pre>
  arg_list <- as.list(args(f))</pre>
  return(length(arg_list))
}
# Create a named vector with the number of arguments in every function
arguments <- map_dbl(funs, ~num_args(.x))</pre>
# Find function with the most arguments
arguments %>%
  sort(decreasing = TRUE) %>%
  head()
##
                                                                   formatC
                       format.default
                                                  source
##
                                                      17
                                                                        16
##
            library merge.data.frame
##
                  14
# Get number of functions with no arguments
(arguments == 0) %>% sum()
```

```
## [1] 25 Should be 225?
```

The scan function has the most arguments at 23 arguments.

There are 25 functions in base with no arguments.
